class08: Machine Learning Mini Project

Peter Shamasha (A15857589)

Breast Cancer Project

Today we aer going to explore some data from the University of Wiscosin Cancer Center on Breast biopsy data.

```
wisc.data <- read.csv("WisconsinCancer.csv", row.names = 1)
head(wisc.data)</pre>
```

Q. how many patients samples are in this dataset?

```
nrow(wisc.data)
```

[1] 569

There are 569 patients in thus dataset.

How many cancer (M) and non cancer (B) samples are there?

```
table(wisc.data$diagnosis)
```

```
B M
357 212
```

Save the diagnosis for later use as a reference to compare how well we do with PCA etc.

```
diagnosis <- as.factor(wisc.data$diagnosis)
#diagnosis</pre>
```

Now exclude the diagnosis column from the data

```
wisc <- wisc.data[, -1]
```

Q. How many "dimensions", "Variables", "columns" are there in this dataset?

```
ncol(wisc)
```

[1] 30

Principle Component Analysis (PCA)

To perform PCA in R we can use the prcomp() function. It takes input as a numeric dataset and optional scale=False/True argument.

We generally always want to set scale=TRUE but let's make sure by checking if the mean and standard deviation values are different across these 30 columns.

```
round( colMeans(wisc) )
```

perimeter_mean	texture_mean	radius_mean
92	19	14
${\tt compactness_mean}$	${\tt smoothness_mean}$	area_mean
0	0	655
symmetry_mean	concave.points_mean	concavity_mean
0	0	0

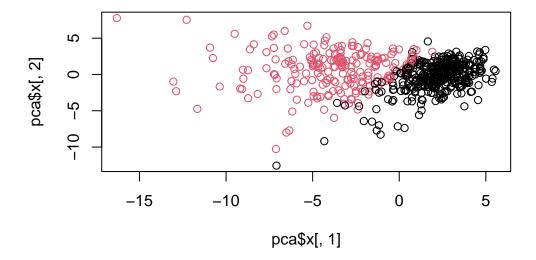

```

```
attributes(pca)
```

```
library(ggplot2)

x <- as.data.frame(pca$x)

ggplot(x) +
   aes(PC1, PC2, col=diagnosis) +
   geom_point()</pre>
```

How much variance is captured in the top 3 PCs.

They captured 72.6% of the total variance.

Q. Q9. For the first principal component, what is the component of the loading vector (i.e. wisc.pr\$rotation[,1]) for the feature concave.points_mean? This tells us

```
pca$rotation["concave.points_mean",1]

[1] -0.2608538

attributes(pca)

$names
[1] "sdev" "rotation" "center" "scale" "x"

$class
[1] "prcomp"
```

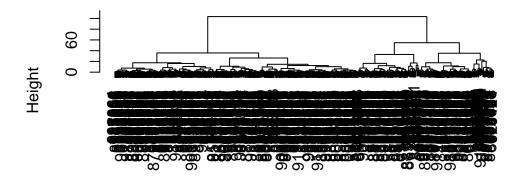

Combine PCA results with clustering.

We can use our new PCA variables (i.e. the scores along the PCs contained in it pca\$x) as input for other methods such as clustering.

```
# Hclust needs a distance matrix as input
d <- dist( pca$x[, 1:3] )

hc <- hclust(d, method = "ward.D2")
plot(hc)</pre>
```

Cluster Dendrogram

d hclust (*, "ward.D2")

To get our cluster membership vector we can use the cutree() function and specify a height (h) ot number of groups (k).

```
grps <- cutree(hc, h=80)
table(grps)

grps
    1      2
203 366</pre>
```

I want to find out how many diagnosis "M" and "B" are in each grp?

```
table(diagnosis)
```

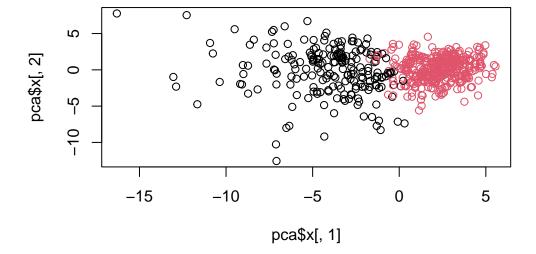

diagnosis B M 357 212

table(diagnosis, grps)

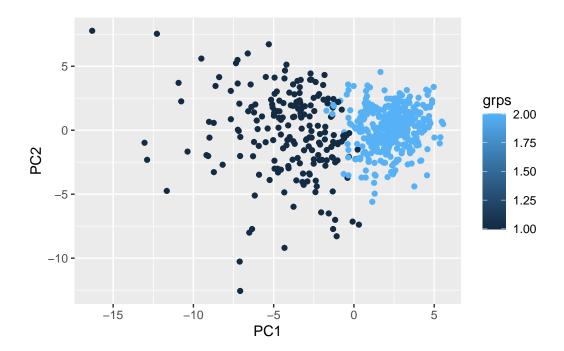

grps diagnosis 1 2 B 24 333 M 179 33

We can also plot our results using our clustering vector grps.

```
plot(pca$x[,1], pca$x[,2], col=grps)
```

```
ggplot(x) +
  aes(PC1, PC2, col=grps) +
  geom_point()
```

Q15. What is the specificty and sensitivity of our current results?

(179/(179+33))

[1] 0.8443396

The sensitivity of our current results is 0.84 or 84%.

333/(333+24)

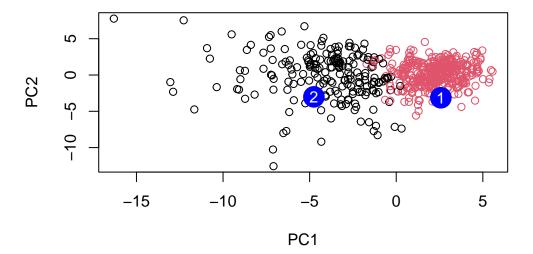

[1] 0.9327731

The specificity of our current results is 0.93 or 93%

Prediction

We will use the predict() function that will take our PCA model from before and new cancer cell data and project that data onto our PCA space.

```
#url <- "new_samples.csv"</pre>
  url <- "https://tinyurl.com/new-samples-CSV"</pre>
  new <- read.csv(url)</pre>
  npc <- predict(pca, newdata=new)</pre>

Q18. Which of these new patients should we prioritize for follow up based on your results?

We should prioritize patient 2 for follow up based on our results because his data falls into the cluster of the malignant group.
